Keywords: Antioxidant, *Corchorus olitorius*, Phytochemical analysis, Oxidative stress, Peroxidation.

Abstract: Oxidative stress is a condition that is characterized by the generation of reactive oxygen species more than the amount endogenous antioxidants can absorb. Several diseases are associated with oxidative stress, notably during disease progression. Thus, the present study aimed to determine the phytoconstituents and antioxidant potential of the ethyl acetate leaf extract of *Corchorus olitorius* (ELEC). The phytochemicals were qualitatively and quantitatively determined, followed by characterization using Fourier-transform infrared (FTIR) spectroscopy. The antioxidant potential was determined in vitro. Alkaloids, saponins, and flavonoids were detected in concentrations of 8.50 ± 2.65 , 11.83 ± 0.73 , and $19.17\% \pm 0.73$, respectively. The FTIR spectrum revealed 9 peaks including six at the group frequency region corresponding to alcohols, carboxylic acid, amine salts, alkenes, alkyne, esters, and oxime functional groups. The ELEC exhibited lower total reducing power (11.06 ± 1.34 AAE $\mu\text{g/ml}$) compared to its total antioxidant capacity (49.26 ± 2.44 AAE $\mu\text{g/ml}$) with a higher ($60.47\% \pm 2.44$) percentage inhibition of peroxidation than AA ($37.98\% \pm 1.88$). Furthermore, the ELEC exhibited a lower (0.20 ± 0.01 nmol/ml) MDA concentration than AA (0.42 ± 0.02 nmol/ml). Conclusively, *C. olitorius* might be applied for the management of oxidative stress-linked ailments and a source of novel therapeutics for these ailments.

Introduction

Oxidative stress is a state of imbalance where reactive oxygen species (ROS) are generated in excess amounts in the body compared to the available endogenous antioxidants. Diseases such as neurodegenerative diseases, diabetes mellitus, cancer, cardiovascular, and other several conditions are associated with oxidative stress (1-4), particularly during the progression stage of the diseases. Thus, creating a disturbance in the balance between the ROS generation and the number of endogenous antioxidants present. Oxidative stress has been coined as an important contributor to carcinogenesis (5). In cancer cells, ROS are generated at a higher rate to allow for the proliferation of the cancer cells. However, these cells generate high amounts of antioxidants to

counter the ROS, thereby preventing the initiation of apoptosis or senescence (6). In neurodegenerative diseases, ROS species don't trigger these diseases. However, they are crucial in aggravating its progression through damaging mitochondrial integration. This leads to mitochondrial dysfunction (7), such conditions include Alzheimer's disease, Parkinson's disease, and Huntington's disease.

Cardiovascular diseases are also associated with oxidative stress leading to the depletion of the available nitric oxide, vasoconstriction, and hypertension. The continued generation of excess ROS leads to disturbance in myocardial calcium handling, arrhythmia, increased cardiac remodeling, and formation of atherosclerotic plaque (8). In diabetes, an

increased metabolic rate generates ROS leading to decreased insulin sensitivity by β -cell and mitochondrial impairment, decreased activity of GLUT-4, inflammatory responses, and disturbance in the insulin signaling pathway (9). Oxidative stress is associated with the progression of many diseases, thus, a vital target for the management of such diseases. Many antioxidant supplements are applied as a remedy for oxidative stress. However, the use of medicinal plants has been in practice for a very long time. Many plants are associated with bioactive compounds and phytochemicals with antioxidant potentials against ROS. These phytoconstituents exert their pharmacological activities against oxidative stress-linked diseases via different mechanisms (10-12). Previous studies reported the in vitro antioxidant activities of different plants demonstrating their radical scavenging activities of the plants (12-17). Thus, exhibiting their therapeutic potential against oxidative stress.

C. olitorius is utilized in traditional medicinal practice in the treatment of malaria, fever, typhoid, and sexual weakness (18). Moreover, the plant is applied in the treatment of dysentery, pain management, and degenerative disorders and is regarded as a potential source of herbal therapeutics to promote health in rural communities in Africa (19). *C. olitorius* also serves as a source of food, phytoconstituents, and pharmaceuticals with good potential for the treatment of diseases and as functional food (20). *C. olitorius* was also reported to exert antibacterial activities, supporting its traditional use against bacterial infections (21). The plant exerts antidiabetic activities with good potential in preventing the postprandial rise in glucose and safety profile (22). An anticancer study revealed that *C. olitorius* exerts its anticancer effects by inducing apoptosis and is effective against colon cancer. Thus, implying its potential in phytotherapy for the management of cancer as opposed to chemotherapy (23). In alcohol liver damage, *C. olitorius* ameliorates liver damage, insinuating its application for the management of alcohol-induced liver damage (24). Thus, in the present study, the phytoconstituents and antioxidant potential of *C. olitorius* were investigated to ascertain its potential in the management of oxidative stress-linked diseases.

Experimental Section

Materials

C. olitorius leaves were obtained from the Yola market of Yola South Local Government, Adamawa State, Nigeria. The plant was identified by a Forest Technologist from the Forestry Technology Department of Adamawa State Polytechnic, Yola where a voucher specimen (ASP/FT/128) was deposited.

The chemicals and reagents used were of analytical grade; Ethyl acetate (LOBA CHEMIE, Loba Chemie PVT. Ltd, India), Potassium ferrocyanide (Amichem Research Lab LLP, India), Trichloroacetic acid (Shree Vissnu Scientific Company, India), Ferric Chloride (Alpha Chemika, India), L-Ascorbic acid (Oxford Lab Fine Chem LLP, India), Sodium phosphate (Research Products International, USA), Ammonium molybdate (Scientific Syndicate, India), Linolenic acid (Shandong Zhi Shang Chemical Co., Ltd., China), Ethanol (Guangdong Guanghua Sci-Tech Co., Ltd., China), Ammonium thiocyanate (Naisha Enterprises, India), Thiobarbituric acid (Isolab Laborgeräte GmbH, Germany), Ferrous chloride (LOBA CHEMIE, Loba Chemie PVT. Ltd, India).

Methods

Sample Extraction

The leaves were dried under shade and ground to powder using a blender. The sample was extracted by the maceration of 200 g of the powder in 1 L of 80% (v/v) ethyl acetate with daily gentle agitation for 7 days at room temperature, followed by filtration and concentration to dryness with a rotary evaporator (Buchi Rotavapor R-200) at 150 rpm under reduced pressure at 40 °C (25).

Phytochemical Analysis

Phytochemicals present in ethyl acetate leaf extract of *C. olitorius* (ELEC) were identified using the method reported previously to detect alkaloids, saponins, steroids, glycosides, terpenoids, and flavonoids (25).

The quantification of phytochemicals was carried out by methods previously reported as follows:

Alkaloids Content

Alkaloids were quantified by the gravimetric method (21). Briefly, 0.5 g of the extract was dispensed into a conical flask containing 10 mL of 10 % ammonium hydroxide to convert alkaloidal salts into the free base; the mixture was stirred and left for 4 h before filtering. The filtrate was evaporated to one-quarter of its original volume on a water bath and concentrated ammonium hydroxide solution was added dropwise to the mixture to precipitate the alkaloids. The precipitate was filtered using a weighed filter paper and washed with 10% ammonium hydroxide solution. The precipitate was dried with the filter paper in an oven at 60°C for 30 minutes and reweighed. The percentage alkaloid content was calculated according to Equation 1.

Saponins

Quantification of saponins was done by the method previously described (26). Briefly, 0.5 g extract was introduced into a conical flask and 10 ml of 20% aqueous ethanol was added. The sample was heated over a water bath for 1 h with continuous stirring at about 55°C. The concentrate was transferred into a

250 ml separator funnel and 5 mL of diethyl ether was added and shaken vigorously. The aqueous layer was recovered and the ether layer was discarded. About 10 ml of n-butanol was then added followed by the addition of 2 ml of 5% aqueous NaCl. The remaining solution was heated over a water bath. After evaporation, the sample was dried in the oven to a constant weight. The percentage saponin content was calculated according to Equation 1.

Flavonoids

Quantification of flavonoids was done by the method described previously (27). Briefly, 0.5g of the extract was mixed with 10 mL of 80% aqueous methanol. The solution was filtered through the Whatman filter paper. The filtrate was transferred to a pre-weighed crucible evaporated into dryness over a water bath and weighed. The percentage flavonoid content was determined according to Equation 1.

$$\text{Total Flavonoid (\%)} = \frac{\text{Weight}_{\text{residue}}}{\text{Weight}_{\text{sample}}} \times 100\% \quad \text{Equation 1}$$

Fourier-transform Infrared Spectroscopy (FTIR) Characterization

FTIR was carried out to determine the functional groups present in ELEC using the Perkin-Elmer FTIR (series 100). Exactly, 0.5 g of the sample was placed directly on the light path to collect the spectra of the reflectance. The readings were recorded with 4000 to 400 cm^{-1} wavelengths at 4 cm^{-1} resolution from 4 scans at 0.2 $\text{cm}^{-1} \text{ s}^{-1}$. Furthermore, the functional groups were determined from the interpretation of the spectrum using the IR spectrum Table (28).

Antioxidant Potential

Total Antioxidant Capacity (TAC)

The TAC was determined by the method described previously (24). Briefly, 0.5 ml of sample (300 $\mu\text{g/ml}$) was mixed with 2 ml of phospho-molybdate reagent (0.6 M H_2SO_4 , 0.028 M sodium phosphate, and 1% ammonium molybdate) and capped. The mixture was incubated at 95 $^{\circ}\text{C}$ for 10 minutes, followed by reading the absorbance at 695 nm against a blank after cooling to room temperature. The blank was made up of the reaction mixtures without the sample. Additionally, different concentrations (20, 40, 60, 80, and 100 $\mu\text{g/ml}$) of AA were used to obtain the standard calibration curve of concentration versus absorbance. The TAC was expressed as AAE in $\mu\text{g/ml}$. All values were determined in triplicates.

Total Reducing Power (TRP)

The TRP was determined as previously described (29). Briefly, 0.25 ml of the sample (200 $\mu\text{g/ml}$) was mixed with 0.625 ml of 1% (w/v) potassium ferrocyanide and 0.625 ml of 0.2 M phosphate buffer (pH 6.6). The mixture was incubated at 50 $^{\circ}\text{C}$ for 20 minutes and 0.625 ml of 10% (w/v) trichloroacetic acid (TCA) was

added, followed by 10 minutes of centrifugation at 3000 rpm and collection of 1.8 ml of the upper layer. Exactly, 1.8 ml of distilled water and 0.36 ml of 0.1% FeCl_3 were added and the absorbance was read at 700 nm against a blank solution of distilled water and the reagents without samples. Additionally, different concentrations (20, 40, 60, 80, and 100 $\mu\text{g/ml}$) of ascorbic acid (AA) treated similarly to the sample were used to obtain the standard calibration curve and determine the ascorbic acid equivalent (AAE) of the samples in $\mu\text{g/ml}$. The TRP was expressed as AAE in $\mu\text{g/ml}$. All values were determined in triplicates.

Ferric Thiocyanate Method (FTC)

The procedure previously described (30) was used to determine the lipid peroxidation inhibitory potential of the extracts. Briefly, 4.1 and 4 ml of 2.52% (v/v) linolenic acid and 1 mg/ml of sample, respectively dissolved in absolute ethanol were mixed with 0.05 M phosphate buffer (pH 7) and 3.9 ml of distilled water. The mixture was capped and incubated for 10 minutes in a dark oven at 40 $^{\circ}\text{C}$. Exactly 0.1 ml of the solution was mixed with 9.7 ml of 75% (v/v) ethanol, 0.1 ml of 30% (w/v) ammonium thiocyanate, and 0.1 ml 0.02 M ferrous chloride in 3.5% (v/v) HCl. The absorbance was initially read 532 nm after adding ferrous chloride. Furthermore, AA was used as standard while the reaction mixture without the sample was used as control. The absorbance was read every 24 hours until the absorbance of the control reached maximum. The percentage inhibition was determined according to Equation 2. All values were determined in triplicates.

$$\% \text{Inhibition} = 100 - \left(\frac{A_t}{A_c} \times 100\% \right) \quad \text{Equation 2}$$

Where A_t = Absorbance of sample while A_c = Absorbance of control.

Thiobarbituric Acid Method (TBA)

The protocol of Kikuzaki and Nakatani (30) was adopted to determine the inhibitory effects of the samples on lipid peroxidation. Exactly 1 ml of the sample and AA solutions from the FTC method were separately mixed with 2 ml of 20% (w/v) TCA and 2 ml of 0.5% (w/v) thiobarbituric acid solution. This was followed by capping, 10 minutes of incubation at 90 $^{\circ}\text{C}$ in a water bath, and 20 minutes of centrifugation at 3000 rpm after cooling. The reaction mixture without the sample or AA was used as a control. The absorbance of the supernatant was read at 532 nm on the last day of the FTC method described earlier. The malonaldehyde (MDA) concentration was determined by Equation 3 using the extinction coefficient 156 $\text{mM}^{-1} \text{ cm}^{-1}$ as previously described (31). All values were determined in triplicates.

$$\text{MDA concentration} = \left(\frac{OD}{EC} \times \text{Sample volume} \right) \quad \text{Equation 3}$$

Where OD = Absorbance of the sample while EC = Extinction coefficient

Statistical analysis

The result obtained was expressed as mean ± standard error of the mean of triplicate determinations (± SEM) and evaluated by independent-samples T-test at p < 0.05 level of significance, using Statistical Package for the Social Sciences (SPSS) version 22 Software.

Result and Discussion

Phytoconstituents of ELEC

The phytochemicals identified in ELEC are presented in Table 1. Alkaloids, saponins, and flavonoids were present while steroids glycoside and terpenoids were absent. Phytochemicals play vital therapeutic roles in the management of different ailments including oxidative stress (32-35).

Table 1. Qualitative phytochemical analysis of C. olitorius leaves.

Phytochemical	Inference
Alkaloids	Present
Saponins	Present
Steroids	Absent
Glycosides	Absent
Terpenoids	Absent
Flavonoids	Present

Alkaloids were reported to influence oxidative stress by inhibiting NADPH-oxidase activity and activating nuclear Nrf2 pathway (36). Neurodegenerative diseases that are linked with oxidative stress were reported to be alleviated by alkaloids, acting as an agonist of muscarinic and adenosine receptors, and also inhibition of anti-amyloid, acetylcholinesterase, butyrylcholinesterase, and α-synuclein aggregation (37). The alkaloid boldine was reported to exert protective effects on the endothelium by preventing the depletion of nitric oxide caused by ROS, thereby, inhibiting the oxidative stress pathway, vital in diabetes and hypertension (38).

Saponins were reported to possess strong antioxidant properties and are implicated in the restoration of mitochondrial function and calcium balance in cells, in addition to inhibiting inflammatory factor synthesis and apoptosis in heart cells (39, 40). Saponins were also reported to exert antioxidant properties by regulating oxidative stress and preventing neuroinflammation and apoptosis (41). In other studies, saponins were reported to exert antioxidants on hypertension by blocking ROS generation and regulating rheology in red blood cells

(42, 43). Saponins also elevate the concentrations of endogenous antioxidants, catalase, and glutathione in serum (44).

Flavonoids exert antioxidative effects by acting on alpha gamma-aminobutyric acid (α-GABA) in epilepsy, associated with elevated production of ROS during seizures, thus showing potential as a therapeutic in epilepsy (45). The generation of ROS is an important factor in the progression of neurodegenerative diseases. Flavonoids act as antioxidants and signaling molecules in slowing down the progression of the disease and improving cognitive performance (46). Quercetin which is another flavonoid exerts neuroprotective properties by preventing ROS damage to DNA through mild intercalation (46). Flavonoids were reported to exert an anti-inflammatory effect credited to their antioxidant properties acting by inhibiting pathways that lead to the generation of ROS (47).

The phytochemicals quantified in the ELEC are shown in Table 2. Flavonoids had the highest concentration (19.17% ±0.73), followed by saponins with a concentration of 11.83% ±0.73 while alkaloids were quantified in the lowest concentration (8.50% ±2.65).

Table 2. Quantitative phytochemical analysis of C. olitorius leaves.

Phytochemical	Concentration (%)
Alkaloids	8.50 ±2.65
Saponins	11.83 ±0.73
Flavonoids	19.17 ±0.73

Values are in triplicate determinations ± SEM.

In a study reported previously, alkaloids, saponins, and flavonoids were detected in leaves of C. olitorius which correlates with the result of the present study (48). The present study also agrees with previous studies for the detection of flavonoids, alkaloids, and saponins in the leaf of C. olitorius (49, 50). In another study on Jute whole plant, only flavonoids were detected with the absence of alkaloids and saponins in the ethyl acetate extract (51). The present study doesn't agree with this study as both saponins and alkaloids were present in ELEC. The present study partially agrees with this study as glycosides were not detected, which might be due to the difference in solvents used for extraction (52). In a similar study, alkaloids, saponins, and flavonoids were detected in ethanol extract of C. olitorius in concentrations of 2.40 ±0.10, 3.32 ±0.02, and 6.30% ±0.10, respectively (53), lower than the values reported in our study (Table 2). The difference in the concentrations might be attributed to the difference in the polarity of solvents used in extraction (52).

Figure 1. FTIR Spectrum of ethyl acetate extract of *C. olitorius*.

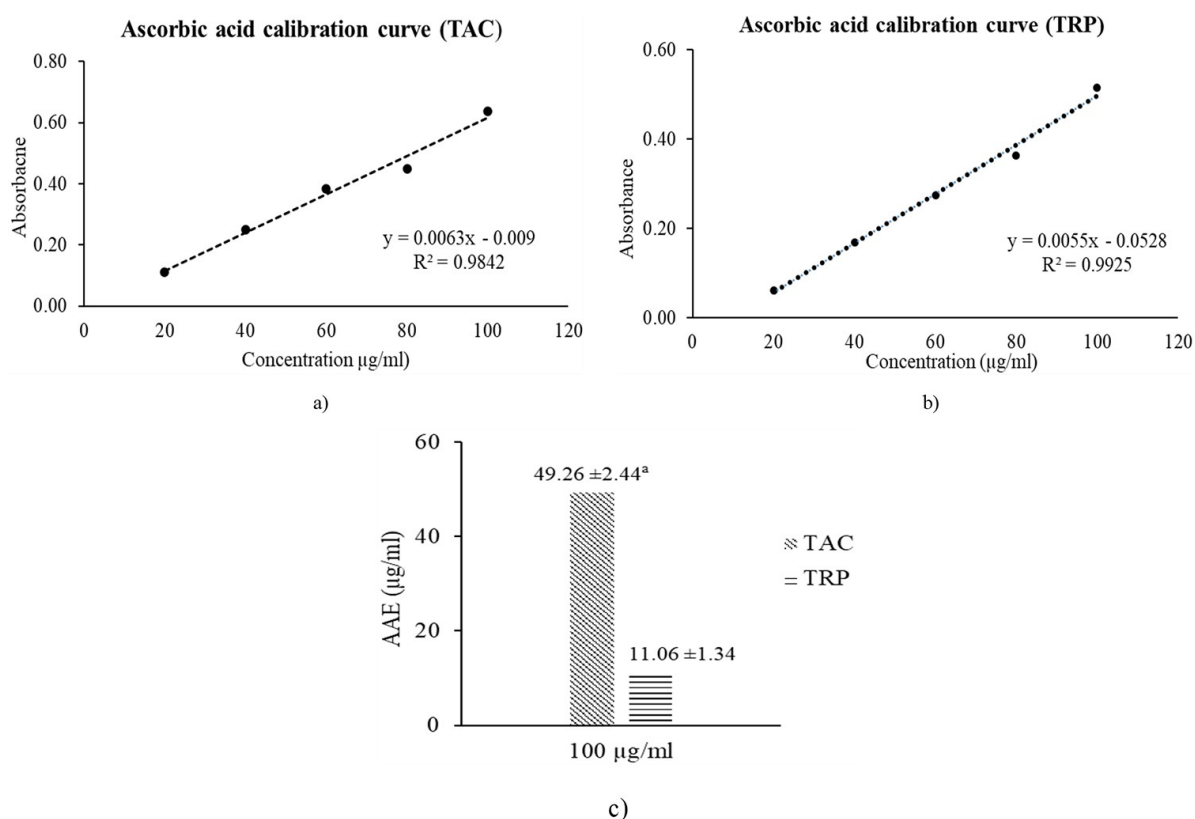

Figure 2. TAC and TRP of ELEC: a) AA calibration curve for TAC, b) AA calibration curve for TRP, and c) AAE TAC and TRP of ELEC. Value with a superscript (TAC) is significantly ($p < 0.05$) higher than the TRP.

Fourier-Transform Infrared (FTIR) Characterization

Figure 1 shows the FTIR spectrum of the ELEC depicting the various peaks. A total of 9 peaks were detected, including six at the group frequency region. The first absorption peak was at 3937.00 cm^{-1}

corresponding to the O-H stretching frequency of free alcohol. The second (3364.2 cm^{-1}) and third (2938.00 cm^{-1}) peak at the frequency regions corresponds to the O-H stretching and N-H stretching frequencies of carboxylic acid and amine salt, respectively. The 2194.9 and 1997.2 cm^{-1} peaks correspond to the $\text{C}\equiv\text{C}$

stretching and C=C stretching frequencies of monosubstituted alkyne and allene respectively while 1693.8 cm⁻¹ corresponds to the C=N stretching of imine/oxime. In the fingerprint region, the peak at 1168.8 (C-O stretching), 861.93 cm⁻¹ (C-H bending), and 558.52 (C-I stretching) fingerprint regions corresponds to the ester, trisubstituted alkane, and halo compound, respectively.

The FTIR spectrum of ELEC presented in Figure 1 shows the presence of different functional groups. Hydroxyl groups were reported to contribute significant antioxidant activities for compounds, including flavonoids and polyphenols, attributed to the electron-donating effects of the OH groups (54). Additionally, the presence of the OH group might also be attributed to the flavonoids detected. The carboxylic acid functional groups detected in the present study were reported to contribute to the antioxidant properties of molecules via transition metal ions chelation (55). Furthermore, the amine groups reported in our study were reported to enhance the antioxidant activities of genistein and its derivatives (56). The presence of oxime was previously reported to enhance the antioxidant activity of naringin compared to pure naringin (57). Additionally, the anti-inflammatory, antioxidant, and anticancer activities of oximes were previously reported (58). Thus, the presence of these functional groups in ELEC might contribute to the antioxidant activities of the plant reported in our study.

Antioxidant Potential of ELEC

Figure 2 presents the TAC and TRP of ELEC, depicting the AA standard calibration curves and the AAE TAC and TRP. The ELEC exhibited a significantly ($p < 0.05$) higher TAC (49.26 ± 2.44 AAE $\mu\text{g/ml}$) compared to its TRP (11.06 ± 1.34 AAE $\mu\text{g/ml}$).

The lipid anti-peroxidation potential of ELEC by the FTC and TBA method is presented in Figure 3 depicting the percentage inhibition and MDA concentration. The ELEC exhibited a significantly ($p < 0.05$) higher ($60.47\% \pm 2.44$) percentage inhibition than AA ($37.98\% \pm 1.88$). Furthermore, the ELEC showed a significantly ($p < 0.05$) lower (0.20 ± 0.01 nmol/ml) MDA concentration than AA (0.42 ± 0.02 nmol/ml).

Free radicals are generated in normal metabolic pathways, however, the presence of endogenous antioxidants that absorb the free radicals prevents oxidative stress due to ROS. Problems arise when the free radicals are produced in amounts higher than can be absorbed by the endogenous antioxidant, a characteristic of many ailments (1-4). A previous study identified phytochemicals such as alkaloids, saponins, and flavonoids to be responsible for the antioxidant properties of plants (59). In another study, these phytochemicals were reported to exert antioxidant effects against lipid peroxidation (53). In our study, the functional groups identified were previously attributed to different antioxidant activities. AA used in the present study exhibited higher TAC and TRP than ELEC which be attributed to its higher antioxidant capacity and the polar nature of the test medium (60). The electron-donating ability of a compound is closely related to its reducing power. In our study, the lower TRP of ELEC might be due to the presence of compounds with poor electron-donating abilities (61). Although AA (polar antioxidant) demonstrated superior TAC and TRP, ELEC exhibited better anti-lipid peroxidation as observed in the FTC and TBA methods where the test medium was non-polar. Moreover, the slightly polar properties of ethyl acetate might lead to the extraction of non-polar antioxidants. Thus, lower peroxidation inhibition and higher MDA concentrations compared to ELEC were observed.

Figure 3. Anti-lipid peroxidation potential of ELEC expressed by: a) FTC and b) TBA methods. Values with a and b superscripts are significantly higher and lower than AA, respectively.

Flavonoids were previously reported to be associated with high free radical scavenging exerting high reducing power and anti-lipid peroxidation (62). In another study, *Zanthoxylum armatum* seeds and barks were reported to exert higher TAC than AA attributed to their flavonoid contents. Furthermore, a correlation was observed between the antioxidant activity and flavonoid content (63). In another study, Saponins exhibited a concentration-dependent reducing power and anti-lipid peroxidation comparable to tannic acid demonstrating its strong antioxidant activity (64). In a similar study, the antioxidant properties of *C. olitorius* using DPPH and ATBS increased with increased concentration (65). *C. olitorius* was previously reported to exert antioxidant properties, attributed to the flavonoids and saponins detected in the study (66). Similarly, a study on the methanol extract of *C. olitorius* using DPPH revealed a concentration-dependent increase in the antioxidant activity of the plant, credited to the phytochemicals reported in the study (49). A similar study reported the antioxidant and antidiabetic effects of the plant and was suggested to be a source of therapeutic for diabetes (67). Ethanol extract *C. olitorius* was previously reported to possess antioxidant properties which were attributed to hydroxyl groups of phenolic compounds (68). The present study revealed the antioxidant potential of ELEC which might be attributed to the phytochemicals and their functional groups.

Conclusion

The present study revealed the presence of phytochemicals that were previously reported to possess different pharmacological properties including antioxidant effects. The presence of alkaloids ($8.50\% \pm 2.65$), saponins (11.83 ± 0.73), and flavonoids ($19.17\% \pm 0.73$) in the ELEC might contribute to the TAC (49.26 ± 2.44 AAE $\mu\text{g/ml}$) and TRP (11.06 ± 1.34 AAE $\mu\text{g/ml}$) exhibited by the extract. Furthermore, these phytochemicals might contribute to the higher anti-lipid peroxidation ($60.47\% \pm 2.44$ percentage inhibition and 0.20 ± 0.01 nmol/ml MDA concentration) than AA ($37.98\% \pm 1.88$ percentage inhibition and 0.42 ± 0.02 nmol/ml MDA concentration). Oxidative stress is associated with several diseases, thus, the antioxidant and anti-lipid peroxidation potential demonstrated by *C. olitorius* makes it a good candidate for the management of oxidative stress in such diseases and might also be a vital source of novel therapeutics against oxidative stress-linked diseases. However, further studies are recommended to identify the specific compounds and their mechanism of action.
